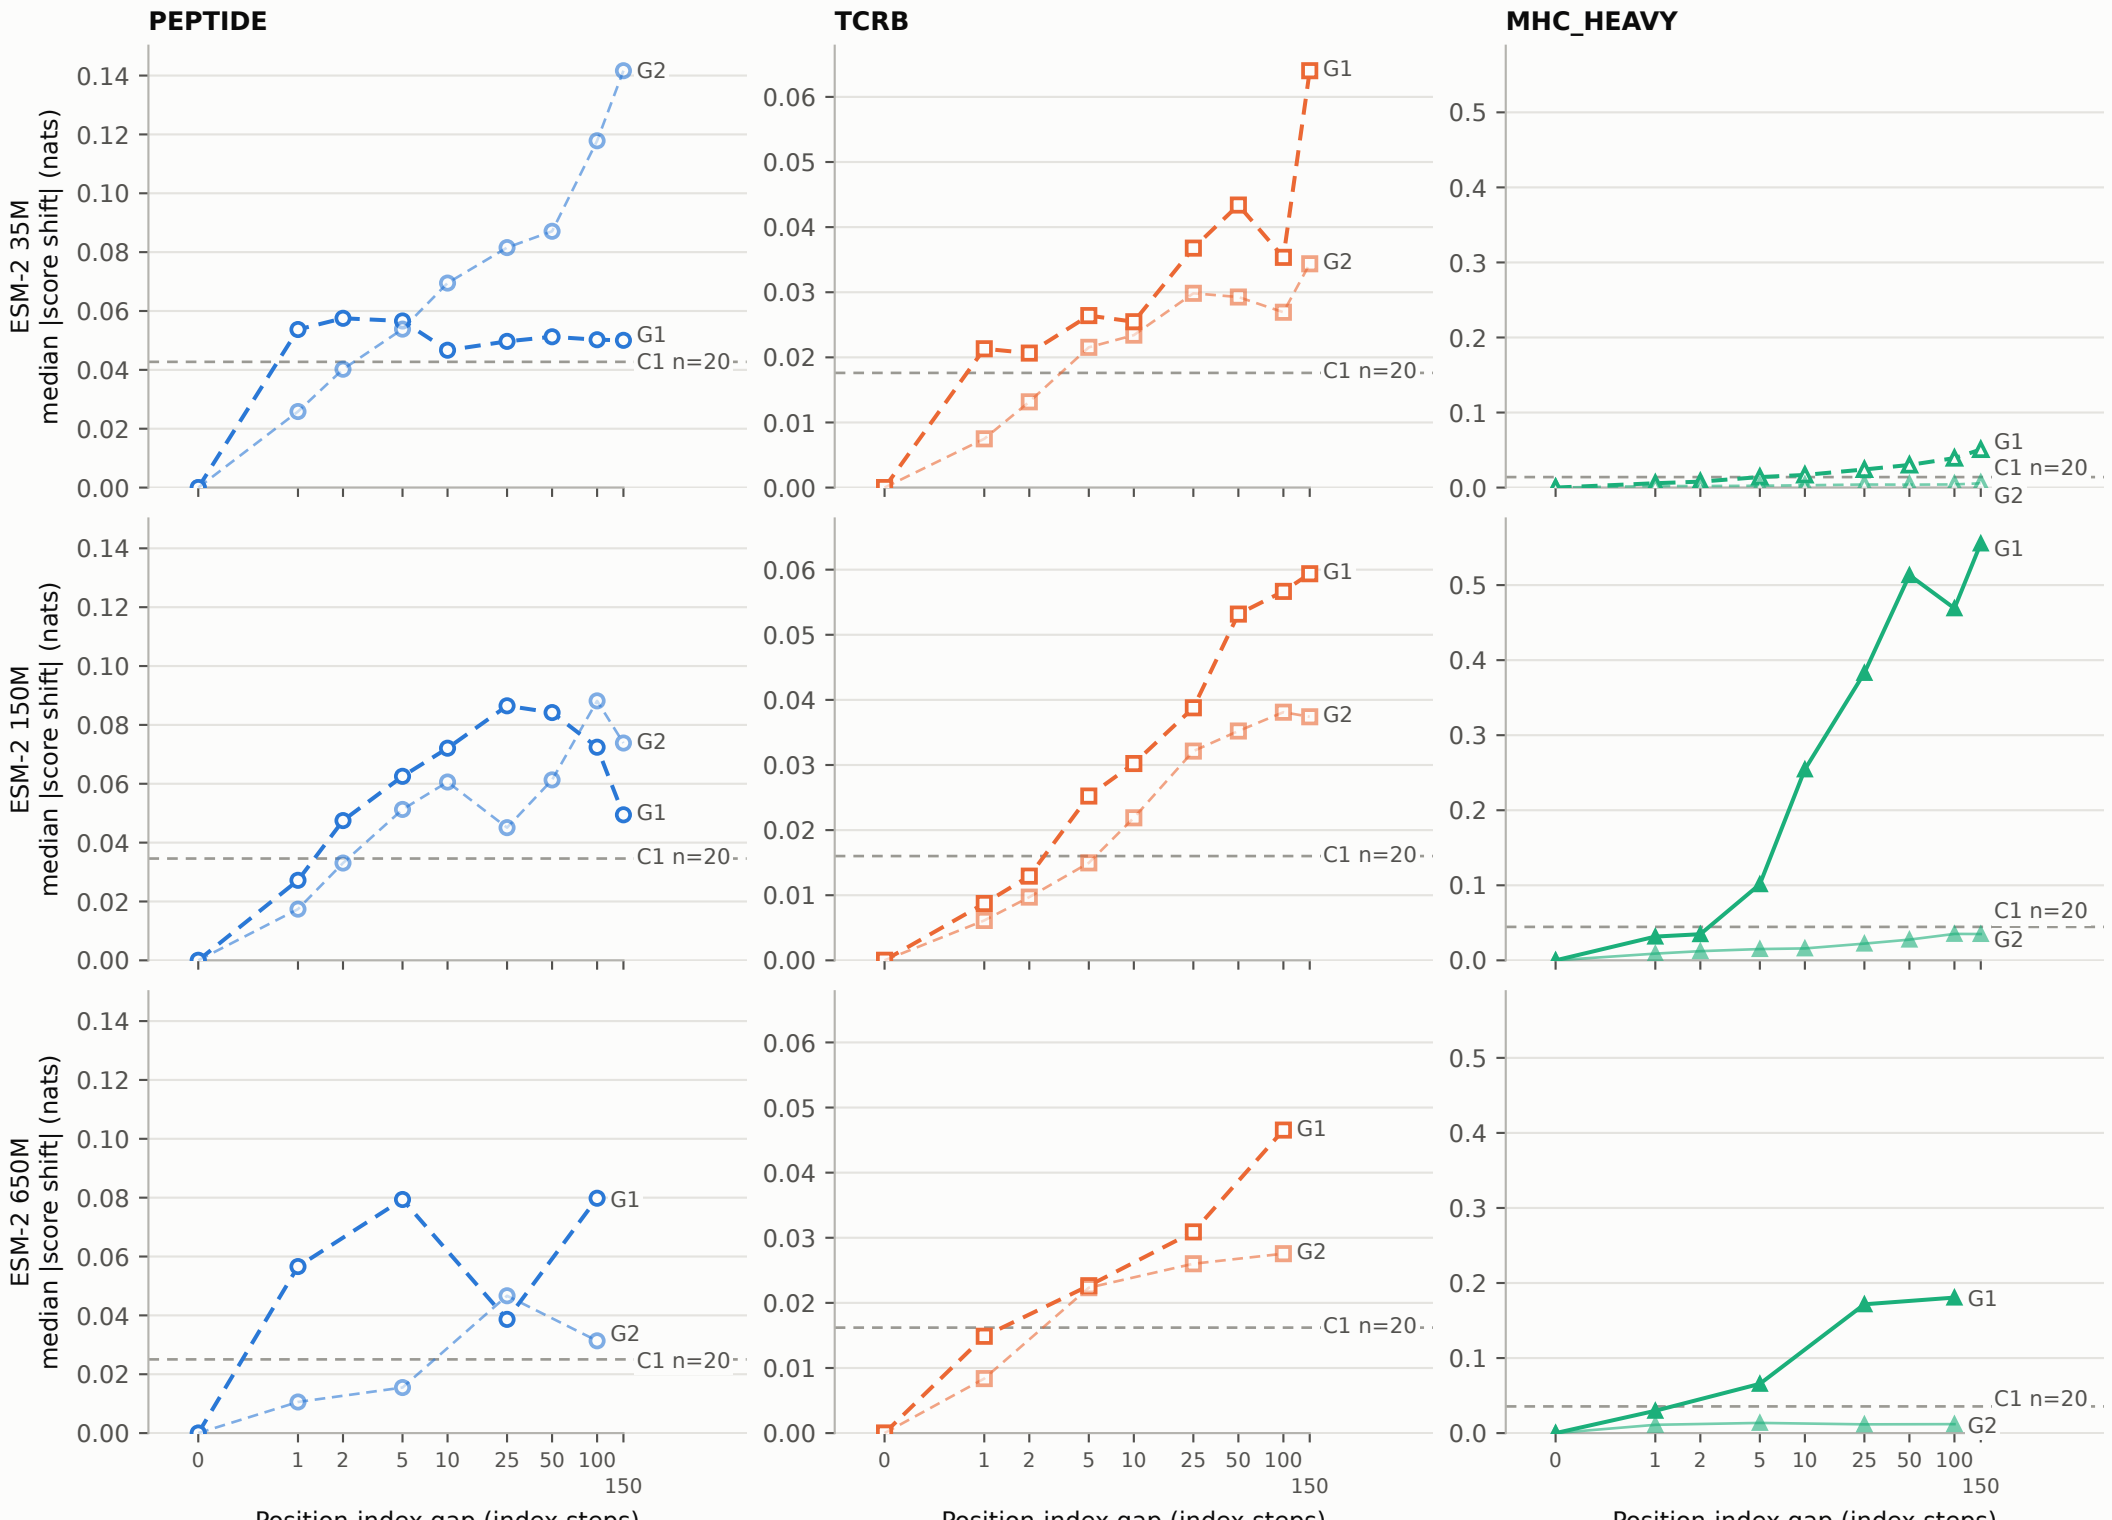
Absolute shifts are small for the peptide and TCR targets, but not for MHC

GSI is a ratio of two small quantities except in the MHC panels, where the shift is large outright.



C1 n=20 (dashed gray): median |shift| from 20 real substitutions, the GSI denominator. G1 full weight, G2 thinner and lighter.
Dashed with hollow markers: estimator fails its sanity check (PEPTIDE and TCRB at every size, MHC at 35M). Y-axis is shared down each column.
